

## Agenda

- Prototype Object
  - Prototype Inheritance
  - Object.create()
- 

Object Instance

Prototype is a property only on constructor functions and is used to define properties and methods that should be inherited by instances created from the constructor.

car.model

car.color

```
▼ Car {model: 'Ford Mustang', year: 2020} ⓘ  
  [model: "Ford Mustang"  
    year: 2020  
    ▼ [[Prototype]]: Object  
      ► displayInfo: f ()  
      ► constructor: f Car(model, year)  
      ► [[Prototype]]: Object
```

## Why use Prototype?

- Saves Memory
  - Promotes efficient code reuse.
- 

## Why not use —proto—?

- Prototype chain manipulation
- Could lead to unexpected behavior in code

Object.create() provides a clean and efficient way to set up inheritance in JS. It allows for the creation of objects with a specific prototype, enabling shared behavior across objects while allowing objects to have individual properties.
